### — Abstract –

In this artefact, we present CrySL, an extensible approach to validating the correct usage of cryptographic APIs. The artefact contains executables for CogniCryPtsast, the analysis CrySL-based analysis, along with the CrySL rules we used

in in the original paper's experiments. We also provide scripts to re-run the experiments. We finally include a tutorial to showcase the CognicRypt\_sast on a small Java target program.

2012 ACM Subject Classification Security and privacy → Software and application security, Software and its engineering → Software defect analysis, Software and its engineering → Syntax & Semantics Keywords and phrases cryptography, domain-specific language, static analysis

Digital Object Identifier 10.4230/DARTS.4.3.6

Related Conference 32nd European Conference on Object-Oriented Programming (ECOOP 2018), July 19–21, 2018, Amsterdam, Netherlands

# 1 Scope

- The artefact is supposed to support repeatability of the experiments in the original paper on a
- $_3$  much smaller scale. In particular, it is designed such that the analysis COGNICRYPT<sub>SAST</sub> may
- 4 be applied to some of the apps we used in our evaluation. Lastly, it facilitates running Cog-
- 5 NICRYPT<sub>SAST</sub> on arbitrary Android and Java applications.

# Content & Usage

- <sup>7</sup> The artefact is a docker container that provides the COGNICRYPT<sub>SAST</sub> analysis, as well as the rule
- sets used for RQ2 and RQ4. We provide the full analysis including a version specifically built to
- analyse Android apps as well as the CrySL rules from our evaluation. We also provide a few test
- apps for the analysis, but have significantly reduced their number compared to the original paper
- because the full analysis takes several days to run even on a 16 core machine with 64 GB RAM.

To set up the docker container, please first download the file called crysl-artefact from the location given in Section 3. The file is a raw docker image that first needs to be imported into the local docker installation before it can be launched. To this end, execute the commands in the directory with the *crysl-artefact* file.

```
docker import crysl-artefact
17
   docker run -ti -v $absolute/Path/on/your/host/system:/home/output
18
       $hash_of_image /bin/bash
19
20
```

The first command imports the image within the file. The docker run command launches a container for the image. The ti option sets up a shell in the container and automatically connects to it. The -v option creates a shared volume between container and host system. The folder /home/output has already been set up, but a directory on the host system needs to be selected that should serve as the shared volume (see \$absolute/Path/on/your/host/system). The directory is used to store the analysis results, facilitating their inspection from the host system. Following that, one needs to specify the image ID, which one can get by executing docker images and then taking the ID of the most recently added image, as well as the initial command /bin/bash to set up and launch the shell in the container.

When running the docker run command, the docker container launches at /. Navigate to /home, in which one may find three folders. First, there is the previously discussed output folder, next to the folders JavaAnalysis and AndroidAnalysis. Folder JavaAnalysis contains a small Java example for the analysis that serves as a tutorial to the artefact and which we describe further in section 2.1. Lastly, folder Android Analysis contains the tools and data to reproduce our results.

#### 2.1 Java Tutorial 35

In the JavaAnalysis directory, one may find several files that all relate to the analysis. First, the CryptoAnalysis.jar comprises the COGNICRYPT<sub>SAST</sub> analysis itself. It further contains the 37 target project FileEncryptor. The project implements a simple file encryption, but contains a few 38 bugs  $COGNICRYPT_{SAST}$  picks up. Finally, the directory CryslRules contains the full  $RULESET_{FULL}$ rule set, both as binaries and in textual form. The latest version of the rules are available at 40 https://github.com/CROSSINGTUD/Crypto-API-Rules. To execute the analysis on the target 41 project, we provide the two scripts runStdOutAnalysis.sh and runFileOutAnalysis.sh. They can 42 be executed as follows: 43

### ./runFileOutAnalysis.sh

The former prints the analysis report to the console, the latter stores them in a file in /home/out-47 put/Javareports (ergo also on the shared folder of the host system). The report file for the tutorial 48 target project is displayed below. The header of the file lists all involved CrySL rules in case the user wishes to check the rule their program violated. The actual findings are grouped by class and 50 further by method name. Each finding contains a short description of the misuse and displays 51 the statement the misuse was found at in Jimple, the intermediate representation the analysis framework Soot [?] we have built COGNICRYPT on operates on. The former is to help the user 53 figure out quickly what they have done wrong and how to fix it, the latter should support them in finding the affected location easily. Applying this structure, the first finding in the report below can be interpreted as "In method encrypt of class Crypto. Enc, the parameter first parameter 56 of the call to Cipher.getInstance() should not just be AES but be extended with one of the 57 elements in the list." We suggest the reader to check out the rules in the docker image or online 58 and either introduce more rule violations to the target program or fix the ones COGNICRYPT<sub>SAST</sub> finds in it.

```
Ruleset:
62
            SecretKey
63
            SecureRandom
65
            Cipher
66
            Signature
67
            KeyGenerator
68
69
            SecretKeyFactory
70
71
   Findings in Java Class: Crypto.Enc
72
     in Method: byte[] encrypt(java.lang.String,javax.crypto.SecretKey)
73
        "AES" should be any of AES/{CBC, GCM, PCBC, CTR, CTS, CFB, OFB}
74
          @r3 = staticinvoke <javax.crypto.Cipher: javax.crypto.Cipher
75
             getInstance(java.lang.String)>("AES")
76
            Variable r2 of type javax.crypto.SecretKey was not properly
77
                generatedKey
78
          @virtualinvoke r3.<javax.crypto.Cipher: void init(int,java.security
79
             .Key) > (1, r2)
80
     in Method: java.lang.String decrypt(byte[],javax.crypto.SecretKey)
81
        "AES" should be any of AES/{CBC, GCM, PCBC, CTR, CTS, CFB, OFB}
82
          @r3 = staticinvoke <javax.crypto.Cipher: javax.crypto.Cipher
83
             getInstance(java.lang.String)>("AES")
84
85
   Findings in Java Class: FileHandler
86
     in Method: java.lang.String performEncryption(java.lang.String)
87
       Object of type byte[] was not properly randomized
88
          @specialinvoke $r4.<javax.crypto.spec.SecretKeySpec: void <init>(
             byte[],java.lang.String)>($r6, "AES")
90
```

## 2.2 Experiments

In the Android Analysis folder, one can find all files related to reproducing our experiments. In directory apps, we provide a few apps along with the artefact in order to facilitate the execution of the analysis. We direct any readers who wish to re-run the full analysis to AndroZoo [?] and Section 8 of our paper in which we outline the selection criteria for the apps. In any case, the folder further contains the rule sets RULESET<sub>FULL</sub> in CogniCryptRules and RULESET<sub>CL</sub> in CryptoLintRules, both in their binary and textual form. We used the RULESETFULL in answering all research questions, the Rulesetcl for RQ4 only. As we analyse Android apps, we require platform files for different versions of the Android SDK in platforms. On top of that, we also need the Android-aware variant of CognicryptoAnalysis-Android-1.0.0-jar-with-dependencies.jar. It comes with some wrapper code that deals the Android-specific content of the apk files and uses Flowdroid [?] for call-graph construction. Once that is done, CogniCryptsast resumes on the remaining Java code. To launch the analysis, execute one of the two runCogniCryptRulesAnalysis.sh or run-CryptoLintRulesAnalysis.sh scripts, depending on which rule set you want applied. Note that we limit the execution time of the analysis to ten minutes by means of timeout. We opted for this solution as the execution time fluctuated heavily between five and 25 minutes on our different testing machines.

The analysis stores its results in /home/output/Androidreports. For each app, a report file following the above described structure is created. Additionally, the analysis summarizes the results in a .csv file.

# 6:4 CrySL: An Extensible Approach to Validating the Correct Usage of Cryptographic APIs (Artifact)

# Getting the artefact

You may download the artefact at https://uni-paderborn.sciebo.de/s/uLtxYDv3Aafob2L.

# 114 **4** Tested platforms

The artefact has been tested with Docker for Windows 10.

# License

The whole artefact licensed under Eclipse Public License (EPL) Version 2.0 (https://www.eclipse.org/legal/epl-2.0/). This does not hold for the apps we provide along with the artefact. They remain licensed under their own license.
